The objective of this paper is to introduce a reciprocal-quadratic difference functional equation and a reciprocal-quadratic adjoint functional equation in copious variables with their geometrical interpretations in Physics and to determine their fundamental stabilities connected with Ulam stability theory in quasi-$\beta$-normed spaces.

Keywords: Rational Function, Reciprocal-Quadratic Function; Functional Equation; Rational Functional Equation; Generalized Ulam-Hyers Stability; Quasi-$\beta$-Normed Space
We also elicit here, a few primitive ideas of quasi-$\beta$-normed spaces. Let $\beta$ be a fixed real number with $0 < \beta \leq 1$ and let $K$ denote either $\mathbb{R}$ or $\mathbb{C}$.

**Definition 1.1** — Let $\mathcal{X}$ be a linear space over $K$. A quasi-$\beta$-norm is a real-valued function on $\mathcal{X}$ satisfying the following conditions: (i) $||u|| > 0$, $\forall u \in \mathcal{X}$ and $||u|| = 0$ if and only if $u = 0$; (ii) $||\mu u|| = |\mu| \beta ||u||$, $\forall \mu \in K$ and $\forall u \in \mathcal{X}$; (iii) there is a constant $K > 1$ such that $||u+v|| < K(||u||+||v||)$, $\forall u, v \in \mathcal{X}$.

The pair $(\mathcal{X}, ||.||)$ is called quasi-$\beta$-normed space if $||.||$ is a quasi-$\beta$-norm on $\mathcal{X}$. The smallest possible $K$ is called the modulus of concavity of $||.||$.

**Definition 1.2** — A quasi-$\beta$-Banach space is a complete quasi-$\beta$-normed space.

In this work, we are interested to ascertain geometrical meaning of the following Reciprocal-Quadratic Difference (RQD) functional equation in several variables

$$r\left(\frac{1}{n} \sum_{i=1}^{n} y_i\right) - r\left(\sum_{i=1}^{n} y_i\right) = \frac{(n^2+1) \prod_{i=1}^{n} r(y_i)}{\left[\sqrt{\sum_{i=1}^{n} r(y_i) \prod_{j=1, j\neq i}^{n} r(y_j)}\right]^2}$$

(1.3)

and Reciprocal-Quadratic Adjoint (RQA) functional equation in several variables

$$r\left(\frac{1}{n} \sum_{i=1}^{n} y_i\right) + r\left(\sum_{i=1}^{n} y_i\right) = \frac{(n^2+1) \prod_{i=1}^{n} r(y_i)}{\left[\sqrt{\sum_{i=1}^{n} r(y_i) \prod_{j=1, j\neq i}^{n} r(y_j)}\right]^2}$$

(1.4)

and to investigate various fundamental stabilities in the framework of quasi-$\beta$-normed spaces.

**Remark 1.3** — When $n = 3$ in the above equations, we have

$$r\left(\frac{y_1 + y_2 + y_3}{3}\right) - r\left(\frac{y_1 + y_2 + y_3}{3}\right) = \frac{8r(y_1)r(y_2)r(y_3)}{\left[\sqrt{r(y_1)r(y_2)} + \sqrt{r(y_2)r(y_3)} + \sqrt{r(y_1)r(y_3)}\right]^2}$$

and

$$r\left(\frac{y_1 + y_2 + y_3}{3}\right) + r\left(\frac{y_1 + y_2 + y_3}{3}\right) = \frac{10r(y_1)r(y_2)r(y_3)}{\left[\sqrt{r(y_1)r(y_2)} + \sqrt{r(y_2)r(y_3)} + \sqrt{r(y_1)r(y_3)}\right]^2}$$

Throughout this paper, let $\mathcal{X}$ be a quasi-$\beta$-normed space and let $\mathcal{Y}$ be a quasi-$\beta$-Banach space with a quasi-$\beta$-norm $||.||_3$. For a given mapping $r : \mathcal{X} \to \mathcal{Y}$, let us define the difference operators

$$D_1 r, D_2 r : \mathcal{X} \times \mathcal{X} \times \ldots \times \mathcal{X} \to \mathcal{Y}$$

by

$$D_1 r(y_1, y_2, \ldots, y_n) = r\left(\frac{1}{n} \sum_{i=1}^{n} y_i\right) - r\left(\sum_{i=1}^{n} y_i\right) = \frac{(n^2-1) \prod_{i=1}^{n} r(y_i)}{\left[\sum_{i=1}^{n} r(y_i) \prod_{j=1, j\neq i}^{n} r(y_j)\right]^2}$$

and

$$D_1 r(y_1, y_2, \ldots, y_n) = r\left(\frac{1}{n} \sum_{i=1}^{n} y_i\right) + r\left(\sum_{i=1}^{n} y_i\right) = \frac{(n^2-1) \prod_{i=1}^{n} r(y_i)}{\left[\sum_{i=1}^{n} r(y_i) \prod_{j=1, j\neq i}^{n} r(y_j)\right]^2}$$

for all $y_1, y_2, \ldots, y_n \in \mathcal{X}$. 

We also assume that \( \sum_{i=1}^{n} y_i \neq 0 \), for all \( y_i \in X, i = 1, 2, \ldots, n \) and \( r(y) \neq 0 \), for all \( y \in X \).

**Geometrical Interpretations of Equations (1.3) and (1.4)**

In this section, we establish the geometrical descriptions of functional equations (1.3) and (1.4) when \( n = 2 \) using Newton's law of gravitation.

Newton's law of universal gravitation states that a particle attracts every other particle in the universe with a force which is directly proportional to the product of their masses and inversely proportional to the square of the distance between their centres.

The force of attraction between object 1 and object 2 is

\[
F(x_1) = \frac{G}{x_1^2}. \tag{2.1}
\]

The force of attraction between object 2 and object 3 is

\[
F(x_2) = \frac{G}{x_2^2}. \tag{2.2}
\]

The force of attraction between object 1 and object 3 is

\[
F(x_1 + x_2) = \frac{G}{(x_1 + x_2)^2}. \tag{2.3}
\]

Using (1), (2) and (3), we have a relation as follows:

\[
F(x_1 + x_2) = \frac{G}{x_1^2 + x_2^2 + 2x_1x_2} = \frac{G}{x_1^2 + x_2^2} \left(1 + \frac{x_1x_2}{x_1^2 + x_2^2}\right) = \frac{G}{x_1^2 + x_2^2} \left(\frac{1}{x_1^2} + \frac{1}{x_2^2} + \frac{2}{x_1x_2}\right) = \frac{F(x_1) + F(x_2) + 2\sqrt{F(x_1)F(x_2)}}{F(x_1) + F(x_2) + 2\sqrt{F(x_1)F(x_2)}}. \tag{2.4}
\]

It is not hard to verify that the reciprocal-quadratic function \( F(x) = \frac{c}{x^2} \), where \( c \) is a constant, is a solution of the above equation (2.4). Thus the reciprocal-quadratic functional equation (2.4) arises in the above physical phenomena.

If the distance between object 1 and object 3 is halved, that is, \( \frac{x_1 + x_2}{2} \), then the force of attraction between them becomes,
The relation between the difference of the forces $F\left( \frac{x_1 + x_2}{2} \right)$ and $F(x_1 + x_2)$ and the forces between object 1 and object 2; and object 2 and object 3 can be modeled as a functional equation as follows:

\[
F\left( \frac{x_1 + x_2}{2} \right) - F(x_1 + x_2) = \frac{3G}{(x_1 + x_2)^2} = \frac{3F(x_1)F(x_2)}{F(x_1) + F(x_2) + 2\sqrt{F(x_1)F(x_2)}}. \tag{2.5}
\]

We call the above functional equation (2.5) as Reciprocal-Quadratic Difference Functional Equation (RQDF Equation) in two variables $x_1$ and $x_2$.

Similarly, the relation between the sum of the forces $F\left( \frac{x_1 + x_2}{2} \right)$ and $F(x_1 + x_2)$ and the forces between object 1 and object 2; and object 2 and object 3 can be modeled as a functional equation as follows:

\[
F\left( \frac{x_1 + x_2}{2} \right) + F(x_1 + x_2) = \frac{5G}{(x_1 + x_2)^2} = \frac{5F(x_1)F(x_2)}{F(x_1) + F(x_2) + 2\sqrt{F(x_1)F(x_2)}}. \tag{2.6}
\]

The above functional equation (2.6) is said to be Reciprocal-Quadratic Adjoint Functional Equation (RQAF Equation) with two variables $x_1$ and $x_2$.

**Fundamental Stabilities of Equations (1.3) and (1.4)**

In this section, we carry out the fundamental stability pertinent to Gavruta and then perpetuate to the stability results of the functional equations (1.3) and (1.4) in quasi-$\beta$-normed spaces pertinent to (Hyers, 1941), (Rassias, 1978) and (Rassias, 1982).

**Theorem 3.1** — Assume $\psi : \mathcal{X} \times \mathcal{X} \times \ldots \times \mathcal{X} \rightarrow [0, \infty)$ is a mapping fulfilling the following inequality:

\[
\sum_{j=0}^{\infty} \left( \frac{K}{n^{2\beta}} \right)^j \psi \left( \frac{y_1}{n^{j+1}}, \frac{y_2}{n^{j+1}}, \ldots, \frac{y_n}{n^{j+1}} \right) < \infty \tag{3.1}
\]

for all $y_1, y_2, \ldots, y_n \in \mathcal{X}$. Suppose $r : \mathcal{X} \rightarrow \mathcal{Y}$ is a mapping which gratifies the ensuing inequality

\[
\| D_1 r(y_1, y_2, \ldots, y_n) \|_y \leq \psi (y_1, y_2, \ldots, y_n) \tag{3.2}
\]

for all $y_1, y_2, \ldots, y_n \in \mathcal{X}$. Then we can construct a unique reciprocal-quadratic mapping $R_d : \mathcal{X} \rightarrow \mathcal{Y}$ satisfying (1.3) and

\[
\| r(y) - R_d(y) \|_y \leq K \sum_{j=0}^{\infty} \left( \frac{K}{n^{2\beta}} \right)^j \psi \left( \frac{y_1}{n^{j+1}}, \frac{y_2}{n^{j+1}}, \ldots, \frac{y_n}{n^{j+1}} \right) \tag{3.3}
\]

for all $y \in \mathcal{X}$. The mapping $R_d(y)$ can be described as

\[
R_d(y) = \lim_{m \to \infty} \frac{1}{n^m} r \left( \frac{y}{n^m} \right), \text{ for all } y \in \mathcal{X}.
\]

**Proof:** Switching $(y_1, y_2, \ldots, y_n)$ to $(\frac{y_1}{n}, \frac{y_2}{n}, \ldots, \frac{y_n}{n})$ in (3.2) and simplifying further, we obtain

\[
\| r(y) - \frac{1}{n^2} r \left( \frac{y}{n^2} \right) \|_y \leq \psi \left( \frac{y_1}{n}, \frac{y_2}{n}, \ldots, \frac{y_n}{n} \right) \tag{3.4}
\]

for all $y \in \mathcal{X}$. Now, replacing $y$ by $\frac{x}{n}$, dividing by $n^{2\beta}$ in (3.4) and summing the resulting inequality with (3.4), we find

\[
\| r(y) - \frac{1}{n^2} r \left( \frac{y}{n^2} \right) \|_y \leq K \sum_{j=0}^{\infty} \left( \frac{K}{n^{2\beta}} \right)^j \psi \left( \frac{y_1}{n^{j+1}}, \frac{y_2}{n^{j+1}}, \ldots, \frac{y_n}{n^{j+1}} \right)
\]
for all \( y \in \mathcal{X} \). Proceeding further in the similar fashion and applying induction arguments on an integer \( m > 0 \), we arrive

\[
\left\| r(y) - \frac{1}{n^{2m}} r\left( \frac{y}{n^m} \right) \right\|_\mathcal{Y} \leq K \sum_{j=1}^{m-1} \left( \frac{K}{n^{2j+2}} \right)^j \psi\left( \frac{y}{n^{j+1}}, \frac{y}{n^{j+1}}, \ldots, \frac{y}{n^{j+1}} \right) \tag{3.5}
\]

for all \( y \in \mathcal{X} \). From (3.4), we obtain

\[
\left\| \frac{1}{n^{2j}} r\left( \frac{y}{n^j} \right) - \frac{1}{n^{2j+1}} r\left( \frac{y}{n^{j+1}} \right) \right\|_\mathcal{Y} \leq \frac{1}{n^{2j}} \psi\left( \frac{y}{n^{j+1}}, \frac{y}{n^{j+1}}, \ldots, \frac{y}{n^{j+1}} \right) \tag{3.6}
\]

for all \( y \in \mathcal{X} \). For \( m > 1 \),

\[
\left\| \frac{1}{n^{2m}} r\left( \frac{y}{n^m} \right) - \frac{1}{n^{2m+1}} r\left( \frac{y}{n^{m+1}} \right) \right\|_\mathcal{Y} \leq \sum_{j=1}^{m-1} \frac{1}{n^{2j+2}} \left\| r\left( \frac{y}{n^{j+1}} \right) - \frac{1}{n^{2j+1}} r\left( \frac{y}{n^{j+1}} \right) \right\|_\mathcal{Y} \tag{3.7}
\]

for all \( y \in \mathcal{X} \). It is easy to find that the right-hand side of the above inequality (3.7) approaches to 0 as \( m \to \infty \) which implies that the sequence \( \left\{ \frac{1}{n^{2m}} r\left( \frac{y}{n^m} \right) \right\} \) is a Cauchy sequence in \( \mathcal{Y} \). Hence, we can delineate

\[
R_d(y) = \lim_{m \to \infty} \frac{1}{n^{2m}} r\left( \frac{y}{n^m} \right)
\]

for all \( y \in \mathcal{X} \). In lieu of \( K \geq 1 \), switching \( y_1, y_2, \ldots, y_n \) to \( \frac{y_1}{n^m}, \frac{y_2}{n^m}, \ldots, \frac{y_n}{n^m} \) and then dividing by \( n^{2m \beta} \) in (3.2), we have

\[
\frac{1}{n^{2m \beta}} \left\| D_r\left( \frac{y_1}{n^m}, \frac{y_2}{n^m}, \ldots, \frac{y_n}{n^m} \right) \right\|_\mathcal{Y} \leq \frac{K^m}{n^{2m \beta}} \psi\left( \frac{y_1}{n^m}, \frac{y_2}{n^m}, \ldots, \frac{y_n}{n^m} \right) \tag{3.8}
\]

for all \( y_1, y_2, \ldots, y_n \in \mathcal{X} \). Allowing \( m \to \infty \) in (3.8) and using the definition of \( R_d \), we observe that \( R_d \) satisfies (3.3) for all \( y_1, y_2, \ldots, y_n \in \mathcal{X} \). Hence \( R_d \) is a reciprocal-quadratic mapping. Also, the inequality (3.5) produces the inequality (3.3). Next to show the uniqueness of \( \mathcal{X} \to \mathcal{Y} \). Presume that there subsists \( R_d : \mathcal{X} \to \mathcal{Y} \) gratifying (1.3) and (3.3). It is easy to show that for all \( y \in \mathcal{X}, R_d\left( \frac{y}{n^m} \right) = n^{2m} R_d(y) \) and

\[
R_d\left( \frac{y}{n^m} \right) = n^{2m} R_d(y)
\]

Then

\[
\left\| R_d(y) - R_d(y) \right\|_\mathcal{Y} = \left\| \frac{1}{n^{2m}} R_d\left( \frac{y}{n^m} \right) - \frac{1}{n^{2m}} R_d\left( \frac{y}{n^m} \right) \right\|_\mathcal{Y} \leq K \sum_{j=0}^{m-1} \frac{1}{n^{2j+2}} \left\| R_d\left( \frac{y}{n^m} \right) - \frac{1}{n^{2j+1}} R_d\left( \frac{y}{n^m} \right) \right\|_\mathcal{Y} + \left\| \frac{1}{n^{2m}} R_d\left( \frac{y}{n^m} \right) \right\|_\mathcal{Y} \leq 2K^2 \sum_{j=0}^{m-1} \frac{1}{n^{2j+2}} \left\| \frac{y}{n^{m+j+1}}, \frac{y}{n^{m+j+1}}, \ldots, \frac{y}{n^{m+j+1}} \right\|_\mathcal{Y} \tag{3.9}
\]

for all \( y \in \mathcal{X} \). By letting \( m \to \infty \), we immediately have the uniqueness of \( R_d \).

The subsequent theorem is dual of Theorem 3.1. Hence, we present the main part of the proof as it is analogous to Theorem 3.1.

**Theorem 3.2** — Let \( \psi : \mathcal{X} \times \mathcal{X} \times \cdots \times \mathcal{X} \to (0, \infty) \) be a mapping gratifying the subsequent inequality:

\[
\sum_{\nu=0}^{\infty} \left( Kn^{2\beta} \right)^\nu \psi\left( n^\nu y_1, n^\nu y_2, \ldots, n^\nu y_n \right) < \infty \tag{3.9}
\]

for all \( y_1, y_2, \ldots, y_n \in \mathcal{X} \). Let \( r : \mathcal{X} \to \mathcal{Y} \) be a mapping
satisfying (3.2) for all \( y_1, y_2, \ldots, y_n \in \mathcal{X} \). Then there subsists an inimitable reciprocal-quadratic mapping \( R_d : \mathcal{X} \to \mathcal{Y} \) satisfying (1.3) and

\[
\|r(y) - R_d(y)\|_y \leq n^{2\beta} K \sum_{j=0}^{m-1} (n^{2\beta} K)^j \psi \left( n^j y, n^j y, \ldots, n^j y \right)
\]  

(3.10)

for all \( y \in \chi \). The mapping \( R_d(y) \) is defined by

\[
R_d(y) = \lim_{m \to \infty} n^{2m} r \left( n^m y \right),
\]

for all \( y \in \chi \).

**Proof:** Switching \((y_1, y_2, \ldots, y_n)\) into \((y, y, \ldots, y)\) in (3.2) and multiplying by \(n^{2\beta}\), we obtain

\[
\|n^2 r(ny) - r(y)\|_y \leq n^{2\beta} \psi (y, y, \ldots, y)
\]  

(3.11)

for all \( y \in \chi \). Now, substituting \( y = ny \), multiplying by \(n^{2\beta}\) in (3.11) and summing the resulting inequality with (3.11), we have

\[
\|n^4 r \left( n^2 y \right) - r(x)\|_y \leq n^{2\beta} K \sum_{j=0}^{m-1} \left( n^{2\beta} K \right)^j \psi \left( n^j y, n^j y, \ldots, n^j y \right)
\]

for all \( y \in \chi \). Using induction arguments on a positive integer \( m \), we conclude that

\[
\|n^{2m} r \left( n^m y \right) - r(y)\|_y \leq n^{2\beta} K \sum_{j=0}^{m-1} \left( n^{2\beta} K \right)^j \psi \left( n^j y, n^j y, \ldots, n^j y \right)
\]

for all \( y \in \chi \). The rest of the proof is analogous to Theorem 3.1.

The following corollaries are immediate consequences of Theorems 3.1 and 3.2 related to the results of (Hyers, 1941), (Rassias, 1978) and (Rassias, 1982).

**Corollary 3.3** — Let \( \varepsilon \geq 0 \) be fixed. If a mapping \( r : \mathcal{X} \to \mathcal{Y} \) satisfies the inequality

\[
\|D_r(y_1, y_2, \ldots, y_n)\|_y \leq \varepsilon, \text{ for all } y_1, y_2, \ldots, y_n \in \mathcal{X},
\]

then there exists a unique reciprocal-quadratic mapping \( R_d : \mathcal{X} \to \mathcal{Y} \) satisfying (1.3) and

\[
\|r(y) - R_d(y)\|_y \leq \frac{n^{2\beta} K \delta}{n^{2\beta + \alpha} - K}, \text{ for all } y \in \chi.
\]

**Proof:** Considering \( \psi (y_1, y_2, \ldots, y_n) = \varepsilon \) in Theorem 3.1, we arrive at the desired result.

**Corollary 3.4** — Let \( \delta \geq 0 \) be fixed and \( \alpha \neq -2\beta \). If a mapping \( r : \mathcal{X} \to \mathcal{Y} \) satisfies the inequality

\[
\|D_r(y_1, y_2, \ldots, y_n)\|_y \leq \delta \sum_{i=1}^{n} \|y_i\|_y^{\alpha}, \text{ for all } y_1, y_2, \ldots, y_n \in \mathcal{X},
\]

then there exists a unique reciprocal-quadratic mapping \( R_d : \mathcal{X} \to \mathcal{Y} \) satisfying (1.3) and

\[
\|r(y) - R_d(y)\|_y \leq \left\{ \begin{array}{ll}
\frac{n^{2\beta + 1} K \delta}{n^{2\beta + \alpha} - K} \|y\|_\chi^\alpha & , \text{for } \alpha > -2\beta, \\
\frac{n^{2\beta + 1} K \delta}{1 - n^{2\beta + \alpha} K} \|y\|_\chi^\alpha & , \text{for } \alpha < -2\beta
\end{array} \right.
\]

for all \( y \in \chi \).

**Proof:** By choosing \( \psi (y_1, y_2, \ldots, y_n) = \delta \sum_{i=1}^{n} \|y_i\|_y^{\alpha} \) and \( \alpha > -2\beta \) in Theorem 3.1 and \( \alpha < -2\beta \) in Theorem 3.2, respectively, we obtain the requisite results.

**Corollary 3.5** — Let \( \delta \geq 0 \) be a fixed real number and a be such that \( \alpha \neq -2\beta \). If a mapping \( R_d : \mathcal{X} \to \mathcal{Y} \) satisfies the inequality

\[
\|D_r(y_1, y_2, \ldots, y_n)\|_y \leq \delta \prod_{i=1}^{n} \|y_i\|_y^{\alpha} \text{ for all } y_1, y_2, \ldots, y_n \in \mathcal{X},
\]

then there exists a unique reciprocal-quadratic mapping \( R_d : \mathcal{X} \to \mathcal{Y} \) satisfying (1.3) and

\[
\|r(y) - R_d(y)\|_y \leq \left\{ \begin{array}{ll}
\frac{n^{2\beta} K \delta}{n^{2\beta + \alpha} - K} \|y\|_\chi^\alpha & , \text{for } \alpha > -2\beta, \\
\frac{n^{2\beta} K \delta}{1 - n^{2\beta + \alpha} K} \|y\|_\chi^\alpha & , \text{for } \alpha < -2\beta
\end{array} \right.
\]

for all \( y \in \chi \).
Proof: By replacing \( \psi(y_1, y_2, \ldots, y_n) = \delta \prod_{i=1}^{n} \| y_i \|^{n/n} \) and considering \( \alpha > -2\beta \) in Theorem 3.1 and \( \alpha < -2\beta \) in Theorem 3.2, we acquire required results.

The following theorems and corollaries are the various stability results investigated for the reciprocal-quadratic adjoint functional equation (1.4). Since arguments of proofs are akin to the above theorems and corollaries, we present the statements only.

**Theorem 3.6** Let \( \psi : \mathcal{X} \times \mathcal{X} \times \ldots \rightarrow [0, \infty) \) be a mapping gratifying the following inequality:

\[
\sum_{j=0}^{n} \left( \frac{K}{n^{2\beta}} \right)^j \psi \left( \frac{y_1}{n^{j+1}}, \frac{y_2}{n^{j+1}}, \ldots, \frac{y_n}{n^{j+1}} \right) < \infty (3.12)
\]

for all \( y_1, y_2, \ldots, y_n \in \mathcal{X} \). Let \( r : \mathcal{X} \rightarrow \mathcal{Y} \) be a mapping such that

\[
\| D_2 r(y_1, y_2, \ldots, y_n) \| \leq \psi(y_1, y_2, \ldots, y_n) (3.13)
\]

for all \( y_1, y_2, \ldots, y_n \in \mathcal{X} \). Then there persists a distinctive reciprocal-quadratic mapping \( R_a : \mathcal{X} \rightarrow \mathcal{Y} \) satisfying (1.4) and

\[
\| r(y) - R_a(y) \| \leq K \sum_{j=0}^{n} \left( \frac{K}{n^{2\beta}} \right)^j \psi \left( \frac{y}{n^{j+1}}, \frac{y}{n^{j+1}}, \ldots, \frac{y}{n^{j+1}} \right) (3.14)
\]

for all \( y \in \mathcal{X} \). The mapping \( R_a(y) \) is defined by

\[
R_a(y) = \lim_{m \to \infty} \frac{1}{n^{2m}} r \left( \frac{y}{n^m} \right) \text{ for all } y \in \mathcal{X}
\]

**Theorem 3.7** — Let \( \psi : \mathcal{X} \times \mathcal{X} \times \ldots \rightarrow [0, \infty) \) be a mapping satisfying

\[
\sum_{j=0}^{n} \left( Kn^{2\beta} \right)^j \psi \left( \frac{n^j y_1, n^j y_2, \ldots, n^j y_n}{n} \right) < \infty (3.15)
\]

for all \( y_1, y_2, \ldots, y_n \in \mathcal{X} \). Let \( r : \mathcal{X} \rightarrow \mathcal{Y} \) be a mapping satisfying (3.13) for all \( y_1, y_2, \ldots, y_n \in \mathcal{X} \). Then there exists a unique reciprocal-quadratic mapping \( R_a : \mathcal{X} \rightarrow \mathcal{Y} \) satisfying (1.4) and

\[
\| r(y) - R_a(y) \| \leq \frac{n^{2\beta} K \delta}{1 - n^{2\beta + \alpha}} \| y \|_1^\alpha \text{ for } \alpha > -2\beta,
\]

\[
\| r(y) - R_a(y) \| \leq \frac{n^{2\beta + \alpha} K \delta}{1 - n^{2\beta + \alpha} K} \| y \|_1^\alpha \text{ for } \alpha < -2\beta
\]

for all \( y \in \mathcal{X} \).

**Corollary 3.8** — Let \( \epsilon > 0 \) be fixed. If a mapping \( r : \mathcal{X} \rightarrow \mathcal{Y} \) satisfies the inequality

\[
\| D_2 r(y_1, y_2, \ldots, y_n) \| \leq \epsilon \text{ for all } y_1, y_2, \ldots, y_n \in \mathcal{X},
\]

then there exists a unique reciprocal-quadratic mapping \( R_a : \mathcal{X} \rightarrow \mathcal{Y} \) satisfying (1.4) and

\[
\| r(y) - R_a(y) \| \leq \frac{n^{2\beta} K \epsilon}{n^{2\beta} - K} \text{ for all } y \in \mathcal{X}.
\]

**Corollary 3.9** — Let \( \delta \geq 0 \) be fixed and \( \alpha \neq 2\beta \). If a mapping \( r : \mathcal{X} \rightarrow \mathcal{Y} \) satisfies the inequality

\[
\| D_2 r(y_1, y_2, \ldots, y_n) \| \leq \delta \sum_{i=1}^{n} \| y_i \|_1^\alpha \text{ for all } y_1, y_2, \ldots, y_n \in \mathcal{X},
\]

then there exists a unique reciprocal-quadratic mapping \( R_a : \mathcal{X} \rightarrow \mathcal{Y} \) satisfying (1.4) and

\[
\| r(y) - R_a(y) \| \leq \frac{n^{2\beta + \alpha} K \delta}{1 - n^{2\beta + \alpha} K} \| y \|_1^\alpha \text{ for } \alpha > -2\beta,
\]

\[
\| r(y) - R_a(y) \| \leq \frac{n^{2\beta} K \delta}{1 - n^{2\beta} K} \| y \|_1^\alpha \text{ for } \alpha < -2\beta
\]

for all \( y \in \mathcal{X} \).

**Corollary 3.10** — Let \( \delta \geq 0 \) be a fixed real number and a be such that \( \alpha \neq -2\beta \). If a mapping \( R_a : \mathcal{X} \rightarrow \mathcal{Y} \) satisfies the inequality

\[
\| D_2 r(y_1, y_2, \ldots, y_n) \| \leq \delta \prod_{i=1}^{n} \| y_i \|_1^\alpha \text{ for all }
\]

for all \( y_1, y_2, \ldots, y_n \in \mathcal{X} \). Let \( r : \mathcal{X} \rightarrow \mathcal{Y} \) be a mapping giving (3.13) for all \( y_1, y_2, \ldots, y_n \in \mathcal{X} \). Then there exists a unique reciprocal-quadratic mapping \( R_a : \mathcal{X} \rightarrow \mathcal{Y} \) satisfying (1.4) and

\[
\| r(y) - R_a(y) \| \leq \frac{n^{2\beta} K \delta}{1 - n^{2\beta} K} \| y \|_1^\alpha \text{ for } \alpha > -2\beta,
\]

\[
\| r(y) - R_a(y) \| \leq \frac{n^{2\beta + \alpha} K \delta}{1 - n^{2\beta + \alpha} K} \| y \|_1^\alpha \text{ for } \alpha < -2\beta
\]

for all \( y \in \mathcal{X} \).
Let \( y_1, y_2, \ldots, y_n \in \mathcal{X} \), then there exists a unique reciprocal-quadratic mapping \( R_d : \mathcal{X} \to \mathcal{Y} \) satisfying (1.4) and

\[
\| r(y) - R_d(y) \|_\mathcal{Y} \leq \begin{cases} 
\frac{n^{2\beta} K \delta}{n^{2\beta + \alpha} - K} \| y \|^2_\mathcal{X}, & \text{for } \alpha > -2\beta, \\
\frac{n^{2\beta} K \delta}{1 - n^{2\beta + \alpha} K} \| y \|^2_\mathcal{X}, & \text{for } \alpha < -2\beta
\end{cases}
\]

for all \( y \in \mathcal{X} \).

**Comparison of The Results of Equations (1.3) and (1.4) With the Existing Literature**

In this section, we compare the results of equations (1.3) and (1.4) with the existing results available in the literature.

The hyper-Ulam stability of reciprocal difference and adjoint functional equations involving two variables with their solutions as multiplicative inverse function \( f(x) = \frac{k}{x} \), were established in the setting of non-zero real numbers by substantiating an inexact solution is close to its correct solution (Ravi et al., 2010c).

In proving hyper-Ulam stability results of the generalized reciprocal type functional equation comprising two variables with solution as \( f(x) = \frac{k}{x} \), it has been proved that there exists an approximate solution near to the precise solution in the setting of non-Archimedean fields (Ravi et al., 2015).

The hyper-Ulam stability results of reciprocal-cubic and reciprocal-quartic functional equations containing two variables with solutions multiplicative inverse cubic and quartic functions, respectively, \( c(x) = \frac{k}{x^3} \) and \( q(x) = \frac{k}{x^4} \), were achieved by showing inexact solutions subsist near to their actual solutions in the framework of non-Archimedean fields (Rassias et al., 2017).

The hyper-Ulam stability of duodecic functional equation with solution as duodecic function \( f(x) = x^{12} \), was demonstrated by determining an approximate solution close to the exact solution in the structure of quasi-\( \beta \)-normed spaces (Rassias et al., 2017).

The hyper-Ulam stability of a quadratic reciprocal functional equation containing two variables only with solution as multiplicative inverse quadratic function \( f(x) = \frac{c}{x^2} \), was proved in the setting of non-Archimedean fields, by validating an approximate solution exists close to the actual solution (Bodaghi and Ebrahimdoost, 2016).

In the above literature, we observe that the hyper-Ulam stability results of rational functional equations were attained in non-Archimedean fields. Inspired by results, in this study, we have dealt new reciprocal-quadratic and adjoint functional equations in several variables with their solution as multiplicative inverse quadratic function and acquired that their hyper-Ulam stability results are still sustainable by showing their approximate solutions exist near to their exact solutions in the setting of quasi-\( \beta \)-normed spaces, which is a different space not dealt so far to investigate hyper-Ulam stability of rational functional equations. Also, this is the first attempt in the theory of functional equations with illustrations of geometric interpretations of rational functional equations in physics.
